1. Introduction to Extend

Extend is a domain-specific programming language used to designate ranges of cells as reusable functions. It abstracts dependencies between cells and models a dependency graph during compilation. In order to offer great performance for any size of datasets, Extend compiles down to LLVM.

Extend's syntax is meant to provide clear punctuation and easily understandable cell range access specifications, while maintaining the look of modern functional programming languages. Given Extend's functionality resonates well with spreadsheets, it borrows syntactical elements from programs such as Microsoft Excel.

2. Structure of an Extend Program

Extend is predominantly composed of function declarations. In order to run the program, the main function will be executed. To illustrate the scope of the language, the OCaml grammar is attached below:

```
/* Ocamlyacc parser for Extend */
%{
open Ast
%}
```

% tokenLSQBRACK RSQBRACK LPAREN RPAREN LBRACE RBRACE

```
\% token COLON COMMA QUESTION GETS EQ SEMI UNDERSCORE
%token SWITCH CASE DEFAULT
%token PLUS MINUS TIMES DIVIDE MOD
%token EMPTY RETURN
%token <int> LIT_INT
\%token <float> LIT_FLOAT
\%token <string> ID
%token EOF
%right QUESTION
%left PLUS MINUS
%left TIMES DIVIDE MOD
%start program
%type <Ast.program> program
%%
program:
    func_decls EOF { List.rev $1 }
func_decls:
    /* nothing */ {[]}
  | func_decls func_decl {$2 :: $1}
func_decl:
    ID LPAREN func_param_list RPAREN LBRACE opt_stmt_list ret_stmt RBRACE
    \{ ((1,1), \$1, \$3, \$6, \$7) \}
```

```
| ret_dim ID LPAREN func_param_list RPAREN LBRACE opt_stmt_list ret_stmt RBRACE
    \{ (\$1, \$2, \$4, \$7, \$8) \}
opt_stmt_list:
    /* nothing */ { [] }
  | stmt_list { List.rev $1 }
stmt_list:
   stmt { [$1] }
  \mid stmt_list stmt { $2 :: $1 }
stmt:
    vardecl { $1 } | assign { $1 }
ret_stmt:
   RETURN expr SEMI \{\$2\}
vardecl:
    ID varassign SEMI \{(\$1, \$2)\}
  | dim ID varassign SEMI {($1, $2, $3)}
varassign:
    /* nothing */ {}
  | GETS expr \{(\$2)\}
assign:
    ID lhs\_sel EQ expr SEMI { (\$1,\$2,\$4) }
```

```
expr:
    ID rhs\_sel \{(\$1,\$2)\}
  | op_expr { $1 }
  | ternary_expr { $1 }
  | switch_expr { $1 }
  | func_expr { $1 } }
  | LPAREN expr RPAREN { $2 }
  | LIT_INT { $1 }
  | LIT_FLOAT { $1 }
  | EMPTY { Empty }
op_expr:
    expr PLUS expr { ($1, $3) }
  \mid \text{ expr MINUS expr } \{ (\$1, \$3) \}
  \mid \text{ expr TIMES expr } \{ (\$1, \$3) \}
  \mid \text{ expr DIVIDE expr } \{ (\$1, \$3) \}
  | \exp MOD \exp \{ (\$1, \$3) \}
ternary_expr:
  /* commented out optional part for now */
    expr QUESTION expr COLON expr %prec QUESTION { ($1, $3, $5) }
switch_expr:
    SWITCH switch_cond LBRACE case_list RBRACE { ($2, List.rev $4) }
switch\_cond:
    /* nothing */ { True }
  | expr { $1 }
```

```
c\,a\,s\,e\, \_\,l\,i\,s\,t\,:
    case_stmt { [$1] }
  | case_list case_stmt { $2 :: $1 }
case\_stmt:

func_param_int_list:
```

```
func_sin_param { [$1] }
  | func_param_int_list COMMA func_sin_param { $3 :: $1 }

func_sin_param:
    ID { ($1) }
    | dim ID { ($1, $2) }

dim:
        LSQBRACK lslice_val RSQBRACK { $2 }
    | LSQBRACK lslice_val COMMA lslice_val RSQBRACK { ($2,$4) }

ret_dim:
    LSQBRACK ret_sin COMMA ret_sin RSQBRACK { ($2,$4) }

ret_sin:
    LIT_INT { $1 }
    | ID { $1 }
    | UNDERSCORE {}
```

3. Types and Literals

3.1. Primitive Data Types

Extend's basic primitives are *integers*, *floats*, *char* literals, and *string* literals. They are all internally represented as numbers or a range of numbers. They are as follows:

Char

A char literal is essentially a size 1 numerical range. At evaluation, the number in the range will be compared with its ASCII equivalent.

String

A string literal is a range of numbers of size n, where n is the length of the string. The string 'hello' can be represented internally as [104, 101, 108, 108, 111].

Integer

A **integer** can be represented as a size 1 numerical range as well. However, it retains its numerical value upon evaluation.

Float

A **float**, like Javascript numbers, can be represented as 64 bit, where the fraction is stored in bits 52 to 62.

Below is a snippet illustrating programmatic declarations for each of the above types.

```
/* Integer */
num = 5;

/* Char */
chr = 'A'

/* String */
str = 'Hello'

/* Float */
num = 1.5;
```

3.2. Ranges

Ranges are a data type unique to the Extend language. It borrows conceptually from spreadsheets; a range is a group of cells with dimensions represented as rows and columns. Each range is either one or two-dimensional. A range is composed of cells, and cells are comprised of functions that can have dependencies on the values of other cells. A range is written as follows:

```
/* This is a left-handed range, used to assign a value. */ [1,2] foo; /*Range with 1 row and 2 columns */
```

3.2.1. Range Slicing

Extend somewhat mimics Python in its range slicing syntax; however, it offers the ability to slice a range in both absolute and relative terms.

```
foo[1,2] /* This evaluates to the cell value at row 1, column 2. */
foo[1,] /* Evaluates to the range of cells in row 1. */
foo[,2] /* Evaluates to the range of cells in column 2.*/
foo[,[1]] /* The internal brackets denote RELATIVE notation.

In this case, 1 column right of the one currently being operated on. */
foo[5:, 7:] /* 5th row down, and 7th column from the absolute origin.
foo[[1:2], [5:7]]

/* Selects the rows between the 1st and 2nd row from current row */
/* Selects the columns between 5th and 7th column from current column */
```

3.2.2. The Underscore Symbol

The underscore(_) symbol allows the dimension of the range to have an unspecified size. For example, in function signatures, using the underscore allows the return value to have various possible dimensions. An example is illustrated below:

```
[1\,,_-] foo; 
/* A range with 1 row and an unknown, variable number of columns. */
```

4. Expressions

- 4.1. Operators
- 4.1.1. Multiplication
- 4.1.2. Addition
- 4.1.3. Unary
- 4.2. Booleans
- 4.3. Variable Declaration
- 4.4. Variable Assignment
- 4.5. Conditionals

5. Functions

Functions lie at Extend's core; however, they are not *first class objects*. Since it can be verbose to write certain operations in Extend, the language will feature a comprehensive number of built-in and standard library function. An important built-in function will be I/O (see section 5).

5.1. Format

Every function in Extend follows the same format, but allows some optional declarations. As in most programming languages the header of the function declares the parameters it accepts and the return type. The simplest function is this:

```
[1,1] foo([1,1] arg) {
  return arg;
}
```

This function simply returns whatever value is passed into it. The leading [1,1] marks the return dimensions. foo is the function name. In parentheses the function arguments are declared, again

with dimensions of the input. The body of the function follows, which in this case is only the return statement.
